Abstract

using online platforms, in part due to the COVID-19 pandemic. Individual replications
have compared the findings of particular experiments online and in-person, but the general
effect of online data collection on data collected from children is still unknown. Therefore,
the current meta-analysis examines how the effect sizes of developmental studies conducted
online compare to the same studies conducted in-person. Our pre-registered analysis
includes 211 effect sizes calculated from 30 papers with 3282 children, ranging in age from
four months to six years. We examined several moderators of the effect of online testing,
including the role of dependent measure (looking vs verbal), online study method

An increasing number of psychological experiments with children are being conducted

(moderated vs unmoderated), and age. The mean effect size of studies conducted in-person

 $_{25}$ was slightly larger than the mean effect size of their counterparts conducted online, a mean

difference of d=.12, but this difference was not significant, 95% CI=[.34, -.09].

²⁷ Additionally, we found no significant moderating effect of dependent measure, online study

28 method, or age.

Conducting developmental research online vs. in-person: A meta-analysis

Public Significance Statement

For many families, interacting with a researcher online could be their first experience with a scientist, providing developmental science with an unprecedented outreach opportunity. However, to ensure that online research lives up to its potential, it is important to understand whether developmental data obtained online is comparable to data collected in-person. The current meta-analysis finds that studies with children conducted online produce generally similar effect sizes as those conducted in-person, which should empower researchers to make the most of this emerging data collection and outreach opportunity.

Introduction

Developmental researchers are interested in studying children's behavior, primarily by
measuring their behavioral responses to experimental stimuli. Study sessions typically
involve visits with local families in a laboratory setting or partnering with remote sites
such as schools and museums. Although these interactions are a routine part of
developmental research, they are time-consuming for both researchers and participants.
Typical studies with dozens of infants or young children can require weeks or months of
scheduling visits to a lab or many visits to testing sites. In-person testing also limits the
participant pool to children living relatively close to the research site. Additionally,
developmental research has been plagued by small, non-diverse samples even more so than
research with adults due to limitations imposed by the demographics of the local
population as well as the high costs of collecting data from children (Kidd & Garcia, 2022;
Nielsen, Haun, Kärtner, & Legare, 2017).

Prior to the rise of video chat software, there were only limited alternatives to in-person interaction for collecting experimental behavioral data from children. However, with the development of inexpensive and reliable video conferencing technology in the
2010s, new frontiers began to emerge for developmental testing. Researchers soon
experimented with conducting developmental studies through video-chat platforms, which
in theory broaden the pool of participants to anyone with access to internet and an
internet enabled device, at nearly any time and location. What began as a few research
teams experimenting with online studies (e.g., Lookit: Scott & Schulz, 2017; The Child
Lab: Sheskin & Keil, 2018; Pandas: Rhodes et al., 2020) quickly expanded to much of the
field as researchers scrambled to conduct safe research during the Covid-19 pandemic. This
shift in research practices has yielded many empirical publications where some or all of the
data were collected online in addition to a growing literature on online methodology and
best practices (for a recent review, see Chuey, Asaba, et al., 2021).

Some researchers may be eager to return to in-person testing, but online research is likely here to stay and may increase in frequency as communications technologies improve and become more accessible. Online testing has immense potential to change developmental science (Sheskin et al., 2020), much as crowdsourced testing of adults has changed adult behavioral science (Buhrmester, Kwang, & Gosling, 2016). This potential has yet to be fully realized, however, as researchers have yet to fully understand the strengths and weaknesses of this method, as well as how to recruit diverse populations for online studies. Despite undersampling certain populations (Lourenco & Tasimi, 2020), online studies nonetheless allow researchers to sample from a larger, broader pool of participants than ever before as access to the internet continues to increase worldwide.

Large, low cost samples and remote cross-cultural research may even become a reality for developmental researchers in the coming years.

Is conducting developmental studies online an effective substitute for conducting them in-person, or do online studies yield systematically different effects? Direct

¹ Observational and survey research has long been conducted through the phone or by mail (e.g., Fenson et al., 1994); here we focus primarily on behavioral observation and experimental methods.

comparison of effects measured in both modalities is critical to answering this question.

Researchers have implemented a number of paradigms online and replicated their in-person findings, but the quality of data yielded from online developmental studies in comparison

to those conducted in-person more broadly is still largely unknown. Therefore, the current

meta-analysis seeks to estimate the effect sizes of data collected from children online and

86 data collected from closely-matched in-person studies.

On the one hand, there is good reason to suspect that modality has little influence 87 over the strength of a study's effect. Fundamentally, studies conducted online and in-person utilize similar measures (e.g., looking time, verbal report) and use similar kinds 89 of stimuli (e.g., moving objects, narrated vignettes). Additionally, experimenters still need to contend with extraneous factors like inattention, environmental distractions, and 91 participants' mood. On the other hand, meaningful differences in online and in-person interactions could affect the outcomes of online and in-person studies, in either direction. In principle, researchers have more control over a child's environment in-person, and in-person studies are usually less susceptible to technical problems such as lag or auditory or visual fidelity issues. Conversely, participants typically complete online studies in a more comfortable, familiar environment - their own home. Any of these factors could tip the scales, yielding larger effects in-person or online; as result, we do not make any predictions regarding the presence or direction of an effect of study modality. Further, online studies themselves are not a monolith, and differ in a multitude of ways including the presence of a 100 live experimenter, dependent measure, and the age of the sample being tested. Such factors 101 could also influence the outcomes of online and in-person studies.

Online studies are generally conducted in one of two formats: moderated or unmoderated. In moderated studies, a live experimenter guides participants through a study much like they would in-person, except online, typically via video-chat. Moderated studies are often operationalized as slides or videos shared with participants while the participants' verbal responses or looking is recorded. In unmoderated studies, conversely,

participants complete a study without the guidance of a live experimenter. Instead, 108 researchers create a preprogrammed module that participants or their parents initiate and 109 complete according to instructions. Since no experimenter needs to be present and 110 participants can participate at any time they choose, unmoderated studies offer the 111 potential for fast, inexpensive data collection. However, since they lack an experimenter, 112 participants' experiences also deviate more from in-person studies compared to moderated 113 studies that retain the same core social interaction between experimenter and participant. 114 Therefore, it is possible that data collected via unmoderated sessions is comparatively 115 noisier since an experimenter is unable to focus children's attention or course correct like 116 they can during a live interaction. We consider this possibility in the current meta-analysis. 117

Like developmental studies more broadly, online studies have also employed a number 118 of dependent measures, including verbal and looking measures. Verbal measures are 119 typically straightforward to record, while recording looking measures is more complex. 120 Accurate looking measures require precise camera positioning and coding schemes, and are 121 thus more likely to deviate from their in-person counterparts compared to studies that 122 measure children's verbal responses. To that end, automated gaze annotation is currently 123 being developed and represents an exciting future direction in online methodology (see Erel, Potter, Jaffe-Dax, Lew-Williams, & Bermano, 2022). We examine how the kind of dependent measure employed (looking vs. verbal) might moderate the difference between online and in-person results. 127

The final moderator we consider is participants' age. Online developmental studies
have sampled from a wide age range, including infants (e.g., Dillon, Izard, & Spelke, 2020),
toddlers (e.g., Lo, Rosslund, Chai, Mayor, & Kartushina, 2021), preschoolers (e.g.,
Schidelko, Schünemann, Rakoczy, & Proft, 2021), and elementary schoolers (e.g., Chuey,
Lockhart, Sheskin, & Keil, 2020; Chuey, McCarthy, et al., 2021). Because online studies
are often conducted in the comfort of their own homes, it is possible that children of all
ages might benefit from this aspect of online studies. Conversely, because a child's

environment is more difficult to moderate online, infant studies, which often rely on precise environmental setups, may suffer more when conducted online. In addition, as children get older they may gain more experience with on-screen displays, which can contribute to their performance in online studies. We test these competing age moderation hypotheses.

In sum, our meta-analysis attempts to estimate the effect sizes of studies conducted with children online and in-person in order to ask whether their outcomes tend to differ across the two modalities, and whether these differences are moderated by study format, dependent variable, or participant age.

143 Methods

We conducted a literature search following the Preferred Reporting Items for 144 Systematic Reviews and Meta-Analyses (PRISMA) procedure (Moher et al., 2015); see 145 Figure 1. For each set of studies determined to be an online replication, we calculated the 146 effect size(s) and associated variance for the main effect of interest. We then conducted a 147 series of random-effects multilevel meta-regressions to estimate the effect of online data collection, as well as three possible moderators (online study method, type of dependent 149 measure, and participant age). Our preregistered data selection, coding, and analysis plan 150 can be found at [anonymous for review]. The list of papers included in this meta-analysis is 151 shown in Table 1.

Literature Search

139

140

141

142

Our goal was to find as many published and unpublished online replications of
developmental studies as possible. However, because there is no common nomenclature for
online replications and the studies themselves cover a wide range of research questions and
methodologies, searching via specific terms or keywords was difficult and produced many
irrelevant papers; as a result, we could not conduct a completely systematic review.

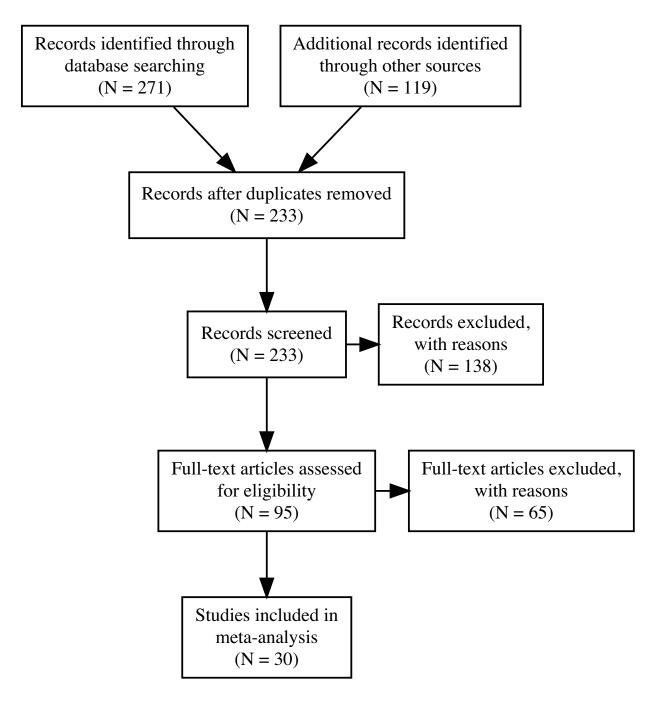

Figure 1. PRISMA plot detailing our study screening process; numerical values represent the number of papers at each stage of the review process.

Instead, we preregistered a forward citation search strategy based on key papers on online developmental research. We used the papers that conducted initial validation of popular 160 online testing platforms as our seeds, including Lookit (Scott, Chu, & Schulz, 2017; Scott 161 & Schulz, 2017), The Child Lab (Sheskin & Keil, 2018), and Pandas (Rhodes et al., 2020). 162 We also included all papers published in the Frontiers in Psychology Special Issue: 163 Empirical Research at a Distance: New Methods for Developmental Science, which largely 164 focused on online developmental studies and replications. Finally, we posted a call for 165 contributions to the Cognitive Development Society (CDS) and International Congress of 166 Infant Studies (ICIS) listservs, two popular emailing lists frequented by developmental 167 researchers. This call yielded several publications our initial search strategy missed, as well 168 as six unpublished but complete online replications. 169

We preregistered several eligibility criteria to filter articles from our search:

170

173

174

175

176

- 1. The study must be experimental, where participants complete a task with a stimulus.

 This criterion precludes surveys or purely observational measures.
 - 2. The studies must report two groups of children, one tested online and another tested in-person. Although the online sample must be collected by the researchers reporting the results, the in-person sample could either be collected at the same time or referenced from an existing publication.
- 3. The mean age of the sample should be under six years. This criterion limits the studies to those conducted on relatively younger children for whom online data collection methods have not been traditionally employed.
- 4. All data reported or referred to must contain codable effect sizes. Verbal comparison alone between an online or in-person study or a qualitative description of results is not enough to determine the precise effect size of interest.

- 5. Data collection for both the in-person and online sample must be complete; any incomplete or partial samples were not considered.
- 185 6. The online and in-person methods must be directly comparable. Some alteration to
 186 the study methods is expected when adapting an in-person study to be run online
 187 (e.g., having children refer to objects by color instead of pointing). However, we
 188 excluded any studies whose methodologies altered the nature of the task or the
 189 conclusions that could be drawn from them (e.g., manipulating the identity of an
 190 object instead of its location).

Table 1

183

184

Papers used in this meta-analysis. Some papers contained both online and in-person results, others contained online replications compared to previous in-person papers. Pairs is number of online – in-person pairs contributed by each paper (set). Look is whether the studies are use looking, verbal, or both types of dependent measures. Mod is whether the online studies were moderated, unmoderated, or both. Age is the average age of the participants in months.

Data Entry

All papers (233) yielded by our search procedure went through three rounds of 192 evaluation to determine if they met our inclusion criteria. First, we screened the titles of 193 the papers to determine whether they might include an online experiment. Those that 194 clearly did not meet one or more of our inclusion criteria were excluded from further 195 evaluation. Next, we performed a similar evaluation based on the papers' abstracts, before 196 a final round based on the article as a whole. All remaining papers were entered into a 197 spreadsheet that coded the necessary information for us to calculate the size of the main 198 effect(s) of interest and their associated variance (sample size, group means and standard deviation, and t and F statistics when applicable), as well as our preregistered moderators (study modality, data collection method, dependent measure, and participant age). 201

If a paper reported an effect size as cohen's d (referred to below as standardized mean difference, SMD), we coded it directly. Otherwise, we calculated the individual effect sizes for each main effect and each study (online and in-person) via reported means and standard deviations, t statistic, or directly from the data if it was available using analysis scripts adapted from Metalab (e.g., Bergmann et al., 2018). If the main comparison was to chance performance, we first calculated log odds and then converted the effect size to cohen's d via the compute.es package in R (Del Re & Del Re, 2012). If a given study had multiple dependent measures or central hypotheses, we calculated an effect size and associated variance for each.

211 Analytic Approach

To determine whether study modality (online or in-person) moderated the size of the main effect of interest for each set of studies, we performed a preregistered random-effects multilevel meta-regression using the metafor package (Viechtbauer, 2010). The regression predicted individual study effect size (SMD) with study modality as a fixed effect,

modeling individual experimental effect sizes with the coefficient of interest being the study 216 modality predictor (online vs. in-person). As discussed above, we did not predict a 217 direction of effect for the study modality predictor. 218

Our approach focused on the study modality moderator, rather than computing a 219 online-offline difference score for each study and estimating the size of that difference 220 directly. Although at a first glance this approach seems simpler, many papers are 221 heterogeneous and contain multiple online studies for a single given offline study, or 222 multiple measures within the same study. In these cases, the appropriate difference was not always clear. For this reason, we chose to enter all study effects into the meta-regression 224 and use the study modality moderator to estimate systematic modality effects.

To ensure that differences in the total number of effect sizes across studies did not 226 bias our analysis by overweighting studies with more measurements, we included two 227 random intercepts in our models. The first random intercept captured variation between 228 particular experiments (e.g., modeling the dependency between multiple measurements 220 reported from a single experiment). The second captured variation between groups of 230 participants (e.g., modeling the dependency between effect sizes from participants who 231 completed a battery of tasks with multiple effects of interest). 232

To determine the effect of additional moderators – online study method (moderated 233 vs unmoderated), dependent measure (looking vs verbal), and participant age - we 234 conducted three additional multilevel meta-regressions each with an additional fixed effect 235 plus the corresponding interaction with study modality. All analysis scripts were 236 preregistered, and the code is available at 237

https://osf.io/up6qn/?view only=91ba54134dc24787b04dd8f3b3b70e1e. 238

Online	Unmoderated	Verbal	1.227	[0.285, 2.169]

Planned Analysis

Overall, the meta-analysis revealed a small negative, non-significant effect of online study modality, Est=-0.12, 95% CI=[-0.34, 0.09], p=0.254. Additionally, we did not find any significant effect of our preregistered moderators or any significant interactions between the moderators and study modality. See Table 2 for coefficient values. Figure 2 shows the effect size differences of experiments by moderators.

Because our meta-analysis averaged across effects from very different paradigms (which could yield different effect sizes independent of the effect of testing modality), we expected substantial heterogeneity. Consistent with that expectation, all tests for residual heterogeneity were highly significant (all ps < .0001). Values of τ^2 (the between-study variance in our meta-analysis) for the models were 0.23 (primary model), 0.23 (moderated vs. unmoderated model), 0.23 (looking-time model), and 0.23 (age model), respectively, confirming the impression that these moderators did not reduce heterogeneity.

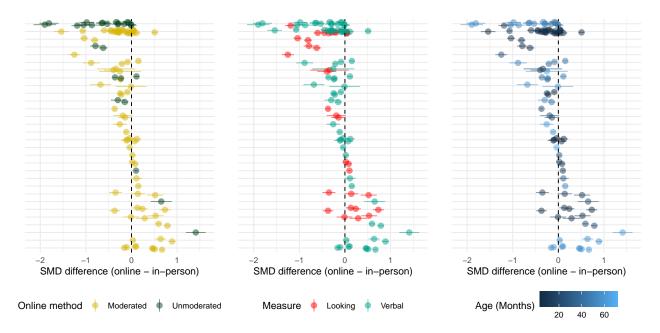

Figure 2. Forest plots of studies, sorted by difference in SMD. Each dot is the difference between and in-person measure and a corresponding online measure. Each row is one study (paper or pair of papers).

253 Exploratory Analysis

In addition to our multi-level meta-analysis, we examined which combinations of 254 methods and measures tended to yield the strongest and weakest effect sizes relative to 255 their in-person counterparts. We fit a meta-analytic model containing method, response 256 mode, and modality as well as their two- and three-way interactions, with the same 257 random effects structure as our previous model. We cannot draw any strong conclusions 258 about these noisy estimates due to our relatively small sample size. That said, 259 unmoderated online studies with looking measures were estimated to have noticeably smaller effect sizes compared to both their moderated online and in-person counterparts, to the extent that their 95% confidence intervals do not overlap (See Table 3). In contrast, as 262 estimated by this model, moderated online studies with looking and verbal measures as 263 well as unmoderated online studies with verbal measures showed no such differences from 264 their in-person counterparts. 265

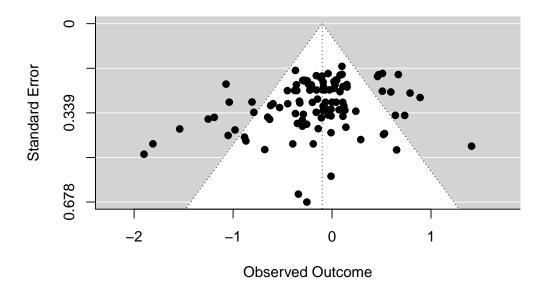

Figure 3. Funnel plot of the differences in effect size between pairs of in-person and online studies. A positive observed outcome means the online study had a large effect.

We also conducted an exploratory analysis of potential publication bias. It was
unclear *a priori* how we might expect publication biases to manifest themselves, given that
there is some possibility of notoriety for either showing *or* failing to show differences
between online and in-person testing. In either case our hypothesized selection process
operated on the *differences* in effect sizes between each online and in-lab pair of samples.

For each online and in-person pair on the same study, we calculated a standard mean 271 difference in effect size between the two studies as well as the variance of this difference. 272 The resulting funnel plot is shown in Figure 3. According to Egger's regression test for 273 funnel plot asymmetry, this plot is asymmetric (p=.005) and the estimated effect assuming 274 no variance is 0.26 [-0.03, 0.55]. This analysis suggests the possibility of publication bias 275 favoring studies that have smaller effect sizes online compared to in-person, signaling that 276 perhaps online studies may have relatively larger effect sizes on average compared to what 277 has been reported. We interpret this conclusion with caution, however, noting the large 278 width of the estimated CI and the relatively low power of Egger's test (Sterne, Gavaghan, 279 & Egger, 2000). 280

281 Discussion

The current meta-analysis provides a birds-eye view of how developmental studies conducted online compare with closely matched counterparts conducted in-person. Our results suggest that overall, in-person developmental studies do not yield significantly larger effect sizes compared to similar studies conducted online. Further, the largest online-offline differences compatible with our estimates are still relatively small. This finding should be heartening for developmentalists interested in using online data collection.

We also examined whether modality effects emerged more substantially in particular settings, but did not find evidence for other moderators. The method of online data collection, type of dependent measure, and participant age did not have a significant impact on the effect of modality. Nonetheless, our lack of statistical precision, indicated by relatively wide confidence intervals, limits our ability to draw strong conclusions about the effect of any of our moderators. Future analysis is needed to determine the moderating effect, if any, that these factors exercise on the outcome of developmental studies conducted online.

The current analysis is coarse-grained, considering only one particular dichotomy 296 within study modality: in-person vs online. Yet, there are many ways that developmental studies can be further subdivided. For example, studies are conducted both in quiet spaces (e.g., in lab, at home) and loud spaces (e.g., parks, museums). Therefore, online studies 299 might over- or under-perform relative to studies conducted in particular in-person 300 locations. Our moderators are also correspondingly course-grained, particularly dependent 301 measure (looking vs verbal). Because our small sample size renders our analysis 302 underpowered to detect weaker effects of moderators, the current results and their 303 interpretation are subject to change as online methods improve and comparisons to 304 in-person studies are better understood. 305

Unmoderated studies with looking measures had the noticeably smallest effect sizes

306

relative to their in-person counterparts. This could reflect the difficulty of both collecting 307 and coding looking data online using participants' own webcams without significant 308 real-time instruction. However, smaller effect sizes online could instead reflect genuinely 309 smaller effect sizes of the underlying effect rather than a lack of online studies' sensitivity. 310 Developmental research has suffered from many failures to replicate in the past, especially 311 studies with infants (e.g., Davis-Kean & Ellis, 2019), and many of the online studies in our 312 sample were conducted after their in-person counterparts, sometimes years later. 313 Therefore, it is possible that smaller online effect sizes simply represent a more accurate 314 estimation of the true (smaller) effect rather than an effect of study modaility per se. 315

The composition of our sample might also bias our results. To match online and 316 in-person methods as closely as possible, we only considered direct online replications for 317 the current meta-analysis. While this approach ensures that data were collected online and 318 in-person using similar methods and procedures, it limits our sample size and may bias our 319 sample. For example, perhaps researchers disproportionately choose to conduct online 320 replications of strong or well-established effects rather than replicate more subtle, weaker 321 effects. Nonetheless, our analysis found that if publication bias exists, it likely favors 322 stronger in-person effect sizes or non-replications among the studies we sampled. We also included an open call for unpublished data in an attempt to limit the file drawer problem (see Rosenthal, 1979).

Although developmental researchers have had decades of experience designing and running experiments in-person, most have only had a few years or less of experience developing online studies. Thus, our meta-analysis might also underestimate the potential of online studies due to researcher and experimenter inexperience. Over the next several years, as developmental researchers develop expertise and experience with online studies, online studies might become more accurate at capturing cognitive constructs for any number of reasons, including better experimenter-participant interactions, better stimulus design (see Chuey, Asaba, et al., 2021), and more accurate methods of measurement (i.e.,

automatic looking time measures, see Erel et al., 2022). Relatedly, as new methods are
developed and adapted for online experiments, researchers should not take the current
findings as a blanket declaration that all online studies produce comparable results to their
in-person counterparts; some might underperform, while others might outperform.

Nonetheless, the current results suggest that across currently employed developmental
methodologies, the effect sizes of studies conducted with children online are generally
comparable to those conducted in-person, especially for studies utilizing verbal measures.

341 Conclusion

Our meta-analysis found that, across closely matched developmental studies
conducted in-person and online, the size of the main effect of interest for in-person studies
did not significantly exceed that of online studies. While our sample of studies limits the
precision of our estimates, nevertheless the general similarity in outcomes for in-person and
online studies with children paint an optimistic picture for online developmental research
more broadly going forward.
